Appendix 2 – Data Completeness by Pollutant	73-82

Introduction

Under the Clean Air Act, the U.S. Environmental Protection Agency (EPA) establishes primary air quality standards to protect public health, including the health of "sensitive populations such as people with asthma, children, and older adults". EPA also sets secondary standards to protect public welfare. This includes protecting ecosystems, including plants and animals, from harm, as well as protecting against decreased visibility and damage to crops, vegetation, and buildings.

EPA has set national ambient air quality standards (NAAQS) for six principal air pollutants (also called criteria pollutants): Ground-Level Ozone (O₃), Particulate Matter (PM), Nitrogen Dioxide (NO₂), Sulfur Dioxide (SO₂), Carbon Monoxide (CO), and Lead (Pb). The Mississippi Department of Environmental Quality (MDEQ) monitors all of these pollutants.

In July 2012, part of DeSoto County was designated as part of the Memphis Nonattainment Area by EPA. However, DeSoto County continues to meet the ozone standard as shown in this report. MDEQ restarted operation of its multi-pollutant site (N-CORE) in July 2013.

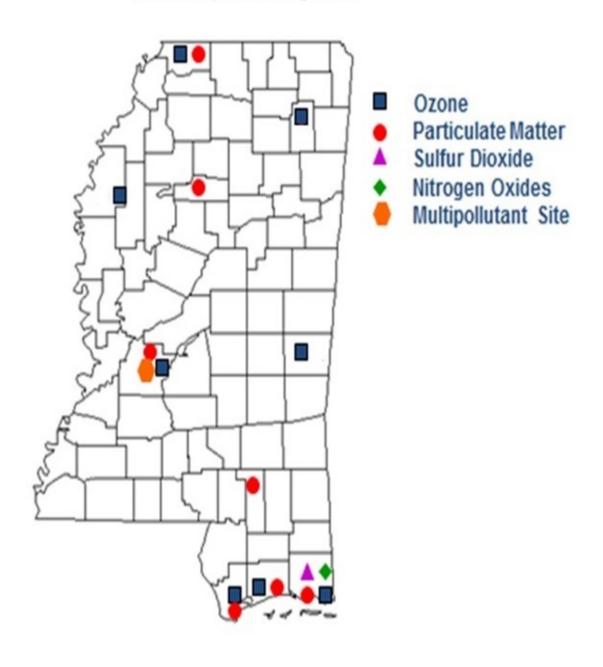

In March 2015, Jackson Metro (Hinds Co. 28.049.0010) FS-19 site was shut down and relocated in April 2015 (Jackson Metro Hinds Co. 28.049.0021) with EPA approval to Hinds Community College, located at latitude 32.346722 and longitude -90.225667.

In October 2015, EPA lowered the primary and secondary ozone standards from 75 ppb to 70 ppb. Although Mississippi is meeting this standard for the 2013-2015 period, EPA will designate attainment/nonattainment areas based on 2014-2016 ozone data.

This report looks at the reported levels of the criteria pollutants in 2015 at various monitoring sites located in Mississippi. It compares these levels to the NAAQS to determine how the state is doing in meeting these standards. As it is stated, Mississippi is meeting all of the NAAQS.

MDEQ Air Monitoring Network

Ground-Level Ozone (O₃)

Ozone is a gas composed of three atoms of oxygen. Ozone occurs both in the Earth's upper atmosphere and at ground level. Ozone can be good or bad, depending on where it is found. It occurs naturally in the stratosphere approximately 6 to 30 miles above the Earth's surface where it forms a protective layer that shields us from the sun's harmful ultraviolet rays. In the Earth's lower atmosphere, near ground level, ozone occurs naturally in lower amounts and additional ozone is formed when nitrogen oxides (NO_x) and volatile organic compounds (VOC_s) emitted by cars, power plants, industrial boilers, refineries, chemical plants, and other sources react chemically in the presence of sunlight. Because this reaction takes time to occur, ozone is usually formed downwind of emission sources.

Ozone is Usually Formed Downwind of Emission Sources

Ozone Standard

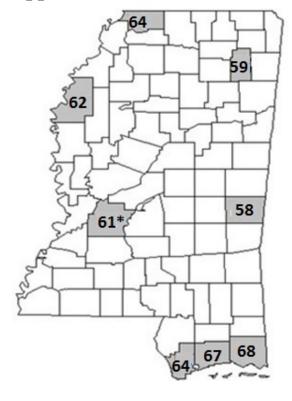

There is one primary and secondary ozone standard – the 8-hour average. MDEQ monitors ozone continuously from March 1 through October 31 each year at the monitoring sites listed below. Ozone is monitored year around at our N-CORE site located in the Jackson MSA.

Primary and Secondary 8-Hour Ozone Standard

The 8-hour standard is met when the 3-year average of the annual fourth highest daily maximum 8-hour average concentration (also known as the design value) is less than or equal to 0.070 parts per million (ppm) or 70 parts per billion (ppb).

8-Hour Ozone Design Values Standard – 70 ppb

Lee County	Tupelo	59

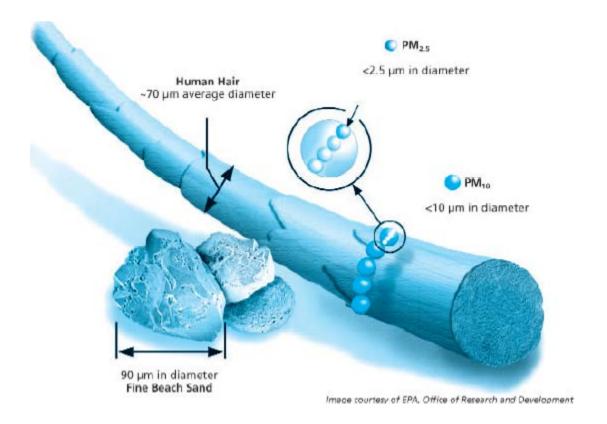

^{*}Incomplete Data: Hinds CC Site not operational until April 2015.

^{*}Incomplete Data: N-CORE Site not operational until July 2013.

Particulate Matter

In general, particulate matter consists of a mixture of larger materials, called "coarse particles", and smaller particles, called "fine particles". Coarse particles have diameters ranging from 2.5 micrometers (μ m) to more than 40 μ m, while fine particles, also known as PM_{2.5}, include particles with diameters equal to or smaller than 2.5 μ m. MDEQ also monitors PM₁₀, which refers to particles less than or equal to 10 μ m in diameter.

These tiny particles come in many shapes and sizes and can be made up of hundreds of different chemicals. Some particles are emitted directly from a source, while others form in complicated chemical reactions in the atmosphere.

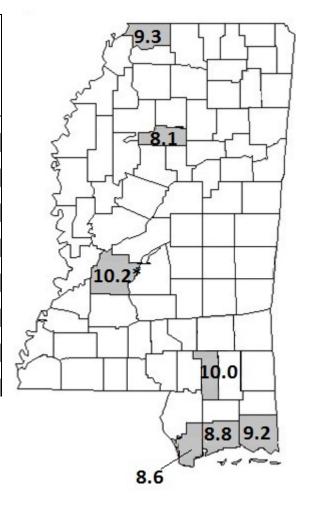

PM_{2.5} Standards

There are two primary and secondary $PM_{2.5}$ standards: (1) Annual Average and (2) 24-Hour Average. MDEQ monitors $PM_{2.5}$ every 3^{rd} day at the monitoring sites listed below.

Primary and Secondary Annual Average Standard – 12.0 μg/m³ and 15.0 μg/m³

The annual average primary standard is met when the three-year average of the annual averages does not exceed 12.0 micrograms per cubic meter ($\mu g/m^3$). The annual average secondary standard is met when the three-year average of the annual averages does not exceed 15.0 micrograms per cubic meter ($\mu g/m^3$).

		2015
		Annual
		Average

Carbon Monoxide

Carbon monoxide (CO) is a colorless, odorless gas that is formed when carbon in fuel is not burned completely. It is a component of motor vehicle exhaust, which contributes about 56% of all CO emissions nationwide. Other non-road engines and vehicles (such as construction equipment and boats) contribute about 22% of all CO emissions nationwide. Other sources of CO emissions include industrial processes, residential wood burning, and natural sources such as forest fires.

Carbon Monoxide Standards

There are two carbon monoxide standards: (1) 8-Hour Average and (2) 1-Hour Standard. MDEQ monitors carbon monoxide continuously year-round at the monitoring site listed below.

<u>Primary CO Standard – 8-Hour 9 ppm</u> 1-Hour 35 ppm

The 8-hour average standard is met if the 8-hour average of 9 parts per million (ppm) is not exceeded more than once per year. The 1-hour average standard is met if the 1-hour average of 35 parts per million (ppm) is not exceeded more than once per year.

		1 - Hour: 1.8

8-Hour Carbon Monoxide

1-Hour Carbon Monoxide

Lead

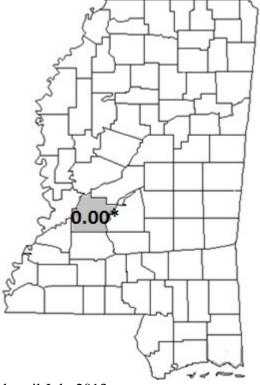

Lead (Pb) is a metal found naturally in the environment as well as in manufactured products. The major sources of lead emissions have historically been from fuels in onroad motor vehicles (such as cars and trucks) and industrial sources. As a result of EPA's regulatory efforts to remove lead from on-road motor vehicle gasoline, emissions of lead from the transportation sector dramatically declined by 95 percent between 1980 and 1999, and levels of lead in the air decreased by 94 percent between 1980 and 1999. Today, the highest levels of lead in air are usually found near lead smelters. The major sources of lead emissions to the air today are ore and metals processing and piston-engine aircraft operating on leaded aviation gasoline.

Lead Standards

Both the primary and secondary standards are calculated by a rolling 3 month average consisting of the most recent 3-year calendar period plus two previous months (*i.e.*, 36 3-month periods), using the last month of each 3-month period as the period of report. MDEQ monitors lead every 6th day at the monitoring sites listed below.

Primary Lead Standard – 0.15 μg/m³

Nitrogen Dioxide

Nitrogen dioxide (NO₂) can often be seen as a reddish-brown layer. Nitrogen dioxide forms when fuel is burned at high temperatures, as in a combustion process. The primary manmade sources of nitrogen dioxide are motor vehicles, electric utilities, and other industrial, commercial, and residential sources that burn fuels. It can also be formed naturally.

Nitrogen Dioxide Standards

There are two NO₂ standards: (1) Annual Average (Primary and Secondary) and (2) 1-Hour Average (Primary). MDEQ monitors nitrogen dioxide continuously year-round at the monitoring site listed below.

<u>Primary and Secondary Annual Average Standard – 53 ppb</u>

The annual average NO₂ standard is met when the annual average does not exceed 53 parts per billion (ppb).

Jackson County	Pascagoula	31

Sulfur Dioxide

Sulfur dioxide (SO_2) belongs to the family of sulfur oxide gases (SO_x). These gases dissolve easily in water. Sulfur is prevalent in all raw materials, including crude oil, coal, and ore that contains common metals like aluminum, copper, zinc, lead, and iron. SO_x gases are formed when fuel containing sulfur, such as coal and oil is burned, and when gasoline is extracted from oil and metals are extracted from ore. SO_2 dissolves in water vapor to form acid, and interacts with other gases and particles in the air to form sulfates and other products that can be harmful to people and their environment.

Over 65% of SO₂ released to the air comes from electric utilities, especially those that burn coal. Other sources of SO₂ are industrial facilities that derive their products from raw materials like metallic ore, coal, and crude oil, or that burn coal or oil to produce process heat. Examples are petroleum refineries, cement manufacturing, and metal processing facilities.

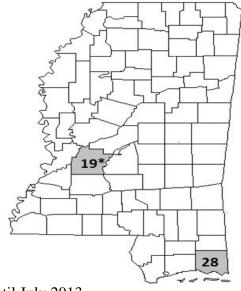

Sulfur Dioxide Standards

There are three primary sulfur dioxide standards – the 1-Hour average, the annual, and the 24-hour average. There is one secondary sulfur dioxide standard – the 3-Hour average. MDEQ monitors sulfur dioxide continuously year-round at the monitoring site listed below.

<u>Primary 1-Hour Average Standard – 75 ppb</u>

The 1-hour average SO₂ standard is met when the three-year average of the annual 99th percentiles of the 1-hour averages does not exceed 75 parts per billion (ppb).

Data Completeness By Pollutant

8-Hour Ozone Data Completeness

Standard

The standards for 8-hour ozone data completeness are:

- The daily maximum 8-hour average concentrations are available for at least 75%, on average, of the designated sampling days for any one year.
- The daily maximum 8-hour average concentrations are available for at least 90%, on average, of the designated sampling days for a three year period.

Nitrogen Dioxide Data Completeness

Standards

The standards for nitrogen dioxide data completeness are:

- An annual mean must be based upon hourly data that are at least 75% complete for the scheduled sampling days in each year.
- A 1-hour design value is valid if it encompasses three consecutive calendar years of complete data. A year meets data completeness requirements when all 4 quarters are complete. A quarter is complete when at least 75% of the sampling days for each quarter have complete data. A sampling day has complete data if 75% of the hourly concentration values are reported.
