Descriptions of Map Units

Alluvium
Flood plain sands, silts, gravels, and clays.

Alluvium derived from the Pre-loess Terrace Deposits and Loess filled valley in Section 14 Township 10N Range 3W.

Alluvial Fans
Alternating silts, sands, and gravels. Coarsest at the apex of the fan, fining laterally (radially) from the apex of the fan.

Jonathan Leard standing on the Yazoo Clay in front of an unconformable contact with a vertical Loess bluff in Section 12 Township 10N Range 3W.

Loess
Silt, buff to tan, pale yellow, red, or gray, sandy to clayey, quartzose to feldspathic. Loess is an eolian deposit derived from glacial outwash. Loess is typically calcareous with dolomite and calcite; however, the upper portion of the loess is highly weathered, leached / noncalcareous, very clayey, and has been referred to as "brown loam." Loess deposits unconformably blanket the pre-loess topography with substantial local variations in thickness. In places, weathered loess contains secondary deposits of small calcareous concretions (caliche, loess dolls). The basal few feet of loess grades into the sands and gravels of the Pre-loess terrace deposits. Loess can be locally and sparingly fossiliferous, commonly containing tests or steinkerns of pulmonate gastropods and less commonly containing fossils of Pleistocene vertebrates such as mastodon, tapir, and ground sloths.

Sioux Quartzite cobble from Pre-loess Terrace Deposits in Section 14 Township 10N Range 3W.

Pre-loess Terrace Deposits
Sand, yellow, orange, purple, red, pink, fine- to coarse-grained, predominantly quartzose, cross-bedded to massive; graveliferous, pebble to large cobble size clasts, clasts of sandstone up to boulder size not uncommon. Gravels are predominantly chert with lesser amounts of vein quartz, metaquartzite, agate, sandstone, and rare rhyolite clasts; clay, pink to white, generally occurring as discontinuous lenses and as rip-up clasts (clast may be boulder size). Conglomeratic ironstone ledges are common in the graveliferous sands at the base of the deposits, which overlies the Cockfield Formation unconformably. "Head-of-hollow," terrace-derived valley fill deposits are common at lower elevations and are isolated to valley walls. These small deposits are of such limited extent as not to warrant representation on this map.

William Pettis with an ice-raftered chart boulder from Pre-loess Terrace Deposits in Section 7 Township 10N Range 2W.

Yazoo Formation (Yazoo Clay)
Clay, calcareous, montmorillonitic, and blue-green color unweathered, marine shell hash common along partings; weathers tan to yellowish-brown with caliche common. Locally fossiliferous; containing beds of the oyster *Pycnodonte trigonalis* and vertebrate remains of the archaeocete whales *Zygorhiza kochii* and *Basilosaurus cetoides*. Selenite locally along joints where clay is frambooidly pyritiferous.

James Starnes chiseling a pedestal of Yazoo Clay containing the partial skeleton of an archaeocete whale, *Zygorhiza kochii*, from Section 14 Township 10N Range 3W.

Moodys Branch Formation
Sandy fossiliferous marl containing an abundance of marine invertebrates typically, *Glycymeris* and *Venericardia* shells. Conformably grades into the overlying Yazoo Formation. Outcrops along the active stream channel of Perry Creek along the border of the non half of Section 13 and 14 and Thompson Creek in the Southeastern 1/4 of Section 12 Township 10 North 3 West due to the influence of Tinsley Dome.

Ice-raftered specimen of the Carboniferous Age fossil *Lepidostrophia* in sandstone from the Pre-loess Terrace Deposits, collected near Tinsley by Jeff McCraw.

Exposure of the unconformable contact between the Moodys Branch and Cockfield formations, along Perry Creek in Section 13 Township 10N Range 3W.

Cockfield Formation
Clay, brown, reddish-brown to grey in color; silty to fine-sandy; strongly carbonaceous to lignitic, slightly micaceous, pyritic. Carbonized and silicified plant fossils common. Underlies the Moodys Branch Formation unconformably. Outcrops along the active stream channel of Perry Creek just north of the border of the center of Section 13 and 14 Township 10 North 3 West near the apex of the influence of Tinsley Dome.

Moodys Branch matrix clast containing mollusk shells of the genus *Glycymeris* and *Venericardia* found as float in Perry Creek in Section 13 Township 10N Range 3W.
